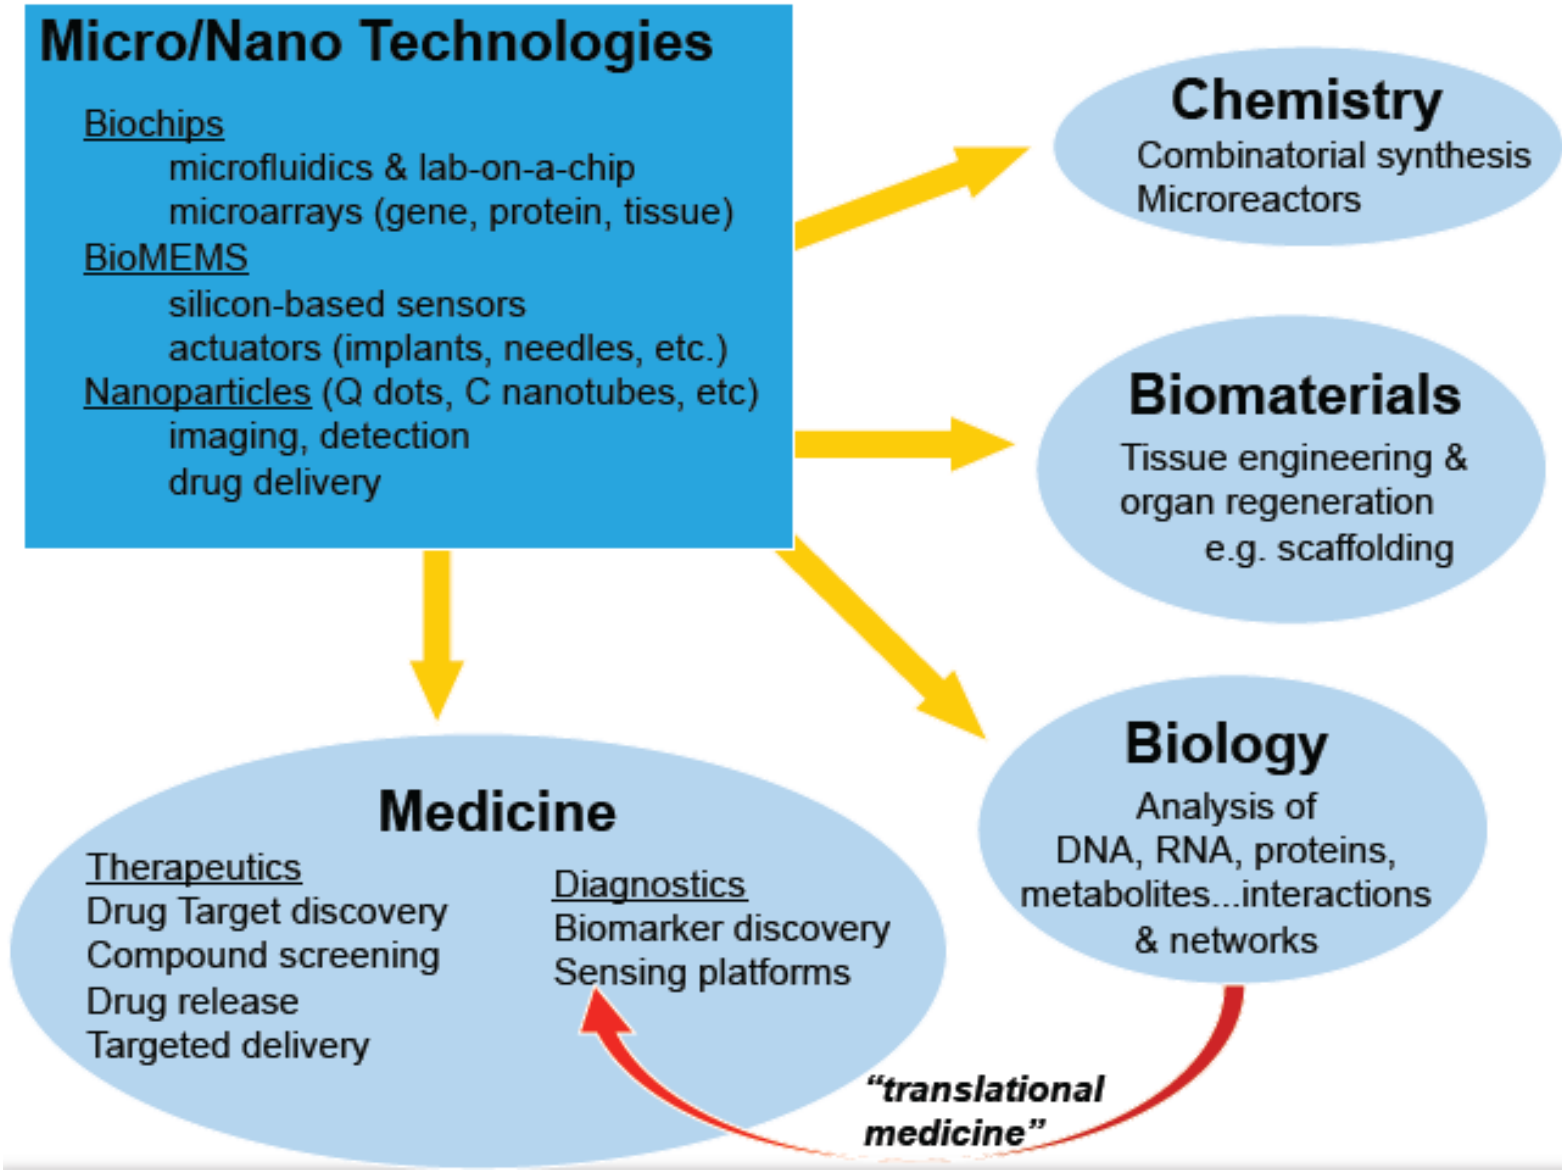
Introduction



Lab-on-a-Chip vs. Microfluidics

Microfluidics is a microtechnological field dealing with the precise transport of fluids (liquids or gases) in small amounts (e.g. microliters, nanoliters or even picoliters).

A Lab-on-a-Chip (LOC) is a device that integrates one or several laboratory functions on a single chip of only millimeters to a few square centimeters in size.

LOCs deal with the handling of extremely small fluid volumes down to less than pico liters. Lab-on-a-Chip devices are a subset of MEMS devices and often indicated by "Micro Total Analysis Systems" (µTAS) as well.

However, strictly regarded "Lab-on-a-Chip" or "µTAS" indicate generally the scaling of single or multiple lab processes to perform chemical analysis.

The term "Lab-on-a-Chip" was introduced later on when it turned out that µTAS technologies were more widely applicable than only for analysis purposes.

History

At beginning of the 1990's, the LOC research started to seriously grow as a few research groups in Europe developed micropumps, flowsensors and the concepts for integrated fluid treatments for analysis systems.

These µTAS concepts demonstrated that integration of pre-treatment steps, usually done at lab-scale, could extend the simple sensor functionality towards a complete laboratory analysis, including e.g. additional cleaning and separation steps.

A big boost in research and commercial interest came in the mid 1990's, when µTAS technologies turned out to provide interesting tooling for genomics applications, like capillary electrophoresis and DNA microarrays. A big boost in research support also came from the military, especially from DARPA (Defense Advanced Research Projects Agency), for their interest in portable bio/chemical warfare agent detection systems.

Point of care diagnostics.

A Promise for Life

i-STAT Analyzer

Fluidigm—the largest commercial μTAS technology company currently in the market—build their microfluidic systems using deformable elastomers (NanoFlex valves).

Advantages

- **Scalable**
- Simple fabrication
- Rapid diagnosis
- Real time
- **Cost effective**
- Portable
- Disposable
- Multiplex diagnosis (arrays)
- User friendly
- High sensitive (Automatic, digital readout)
- **Flexible**
- Easy to store
- Avoid damage during transportation
- The wettablility of paper help biosensing without external follow control systems
- Directly sensing (not depends on enzyme reaction)
- Enhance the healthcare in extreme places such as developing world and battle fields.

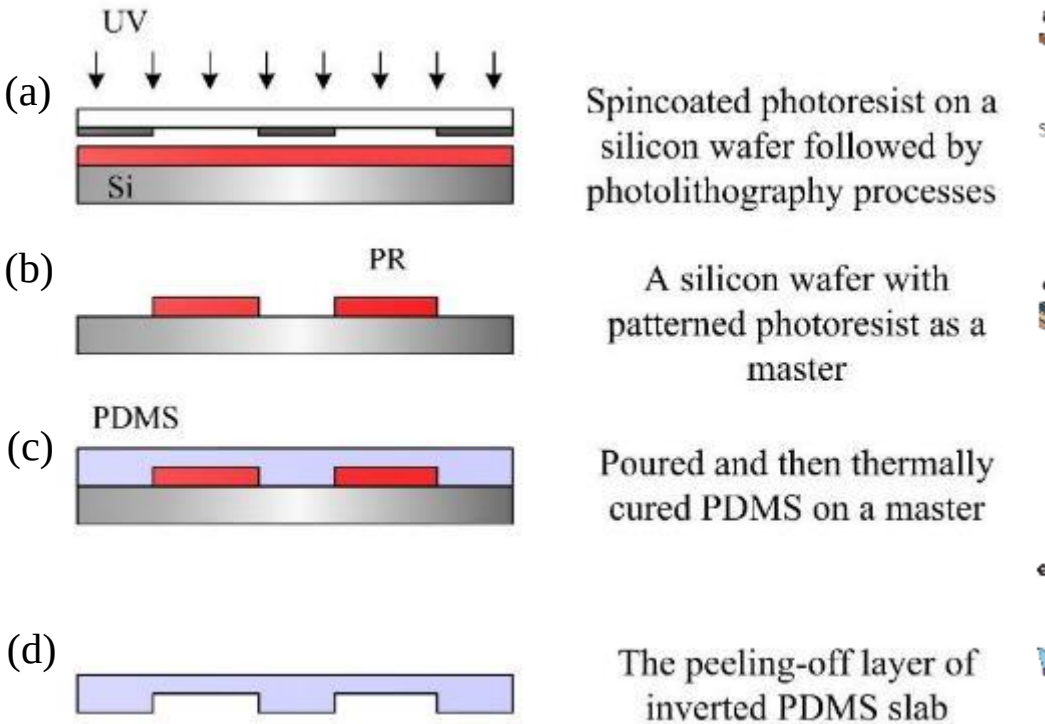
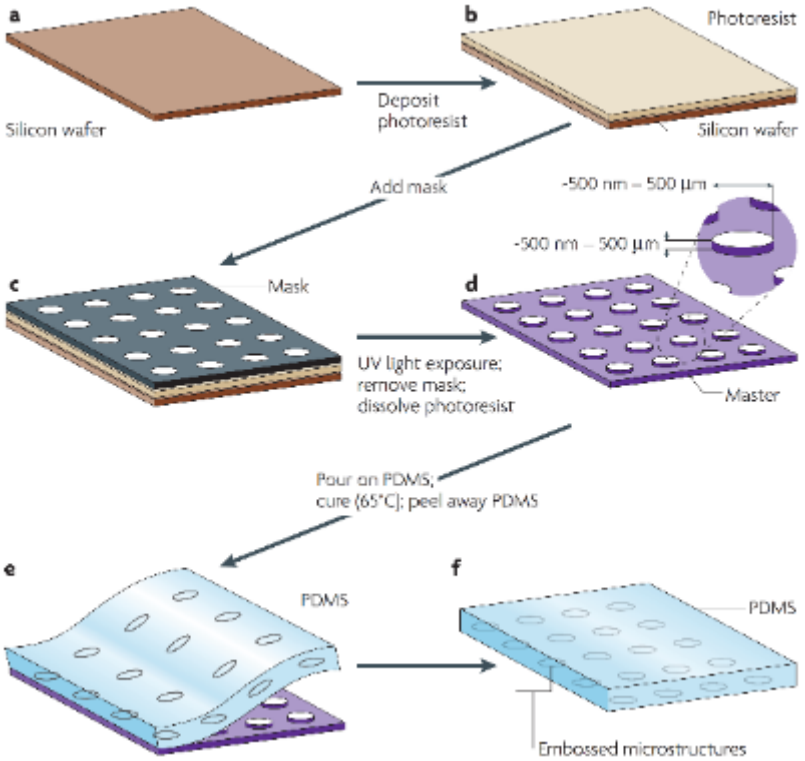
CTE: coefficient of thermal expansion

The variance of these parameters is based on the different grades of polymer.

Soft Lithography

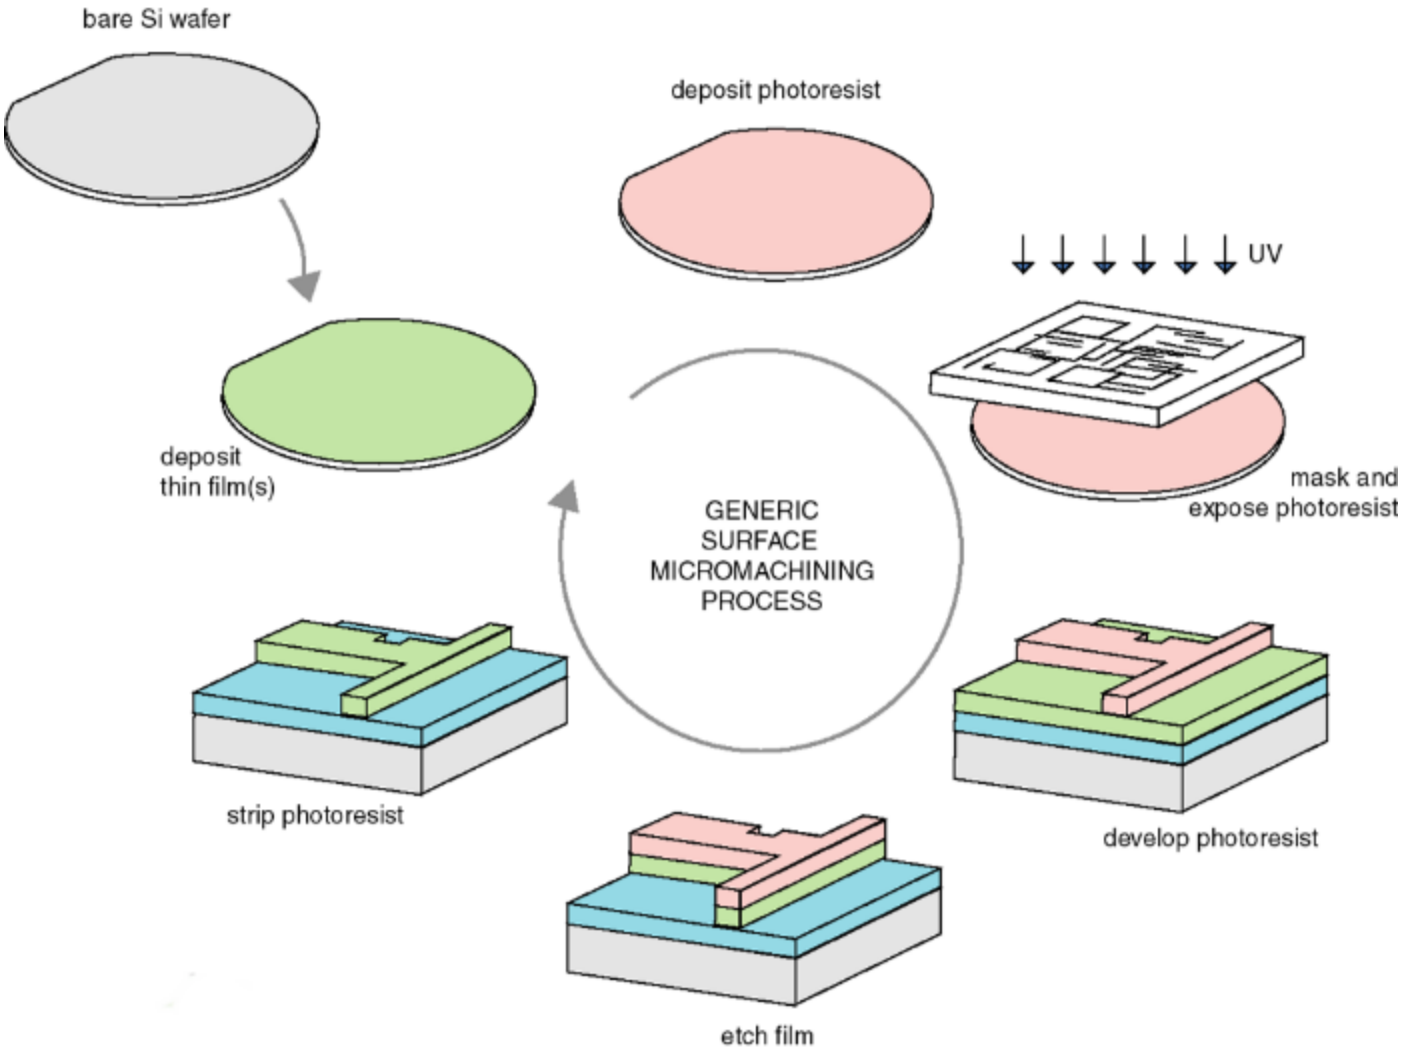




The fabrication of PDMS slab using soft lithography. (ab) Master is first formed by spincoated photoresist on a silicon wafer followed by photolithography processes. (c) PDMS mixture is then poured on the master and cured thermally. (d) The peeling-off layer of PDMS slab has invert microstructures to the master.

The fabrication of micropatterned slabs of PDMS. (a–d) Photoresist is spincoated on a silicon wafer followed by photolithography processes. As a result, the master consists of a silicon wafer with features of photoresist in bas-relief. (e) PDMS is poured on the master and then cured thermally. (f) The peeling-off layer of PDMS has invert microstructures embossed in its surface.
D. B. Weibel, W. R. DiLuzio and G. M. Whitesides, *Nature Reviews Microbiology*, 2007, **5**, 209-218.

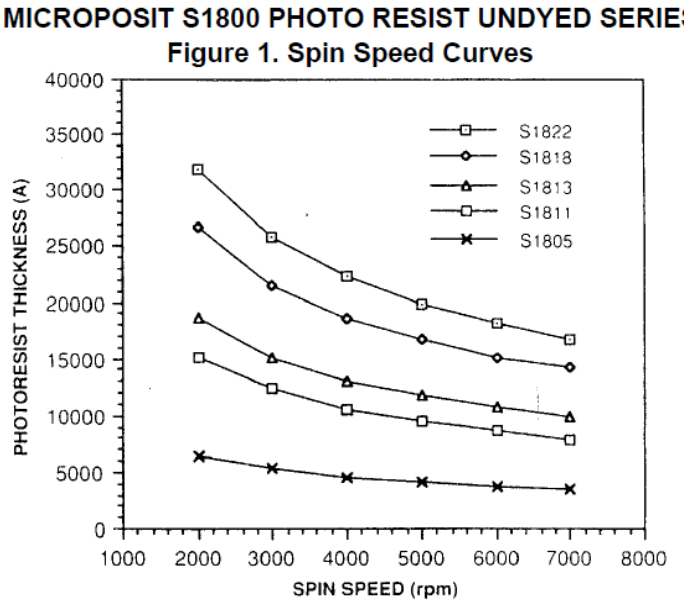
Typical Micromachining Process

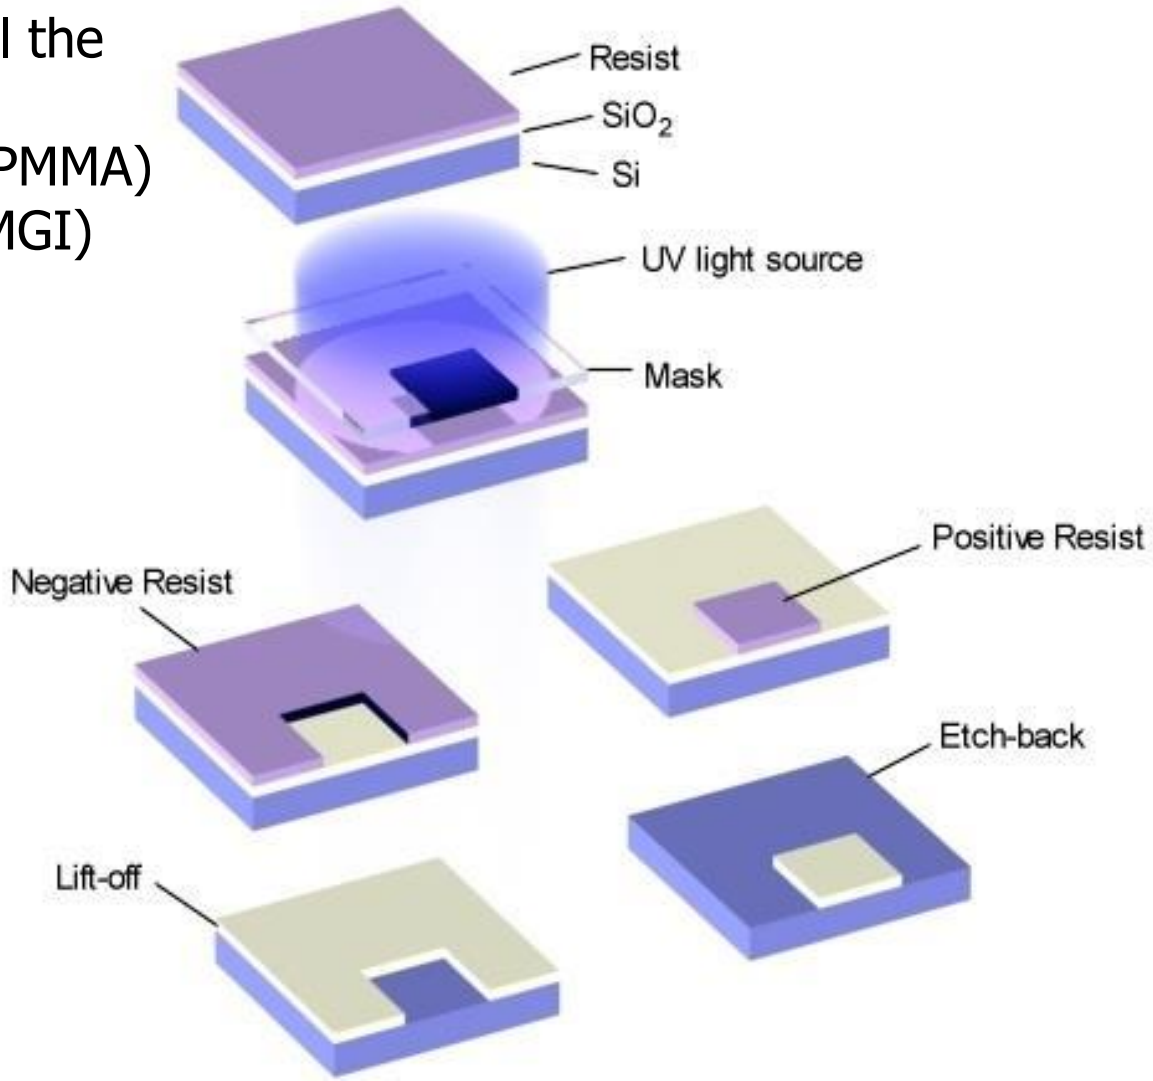


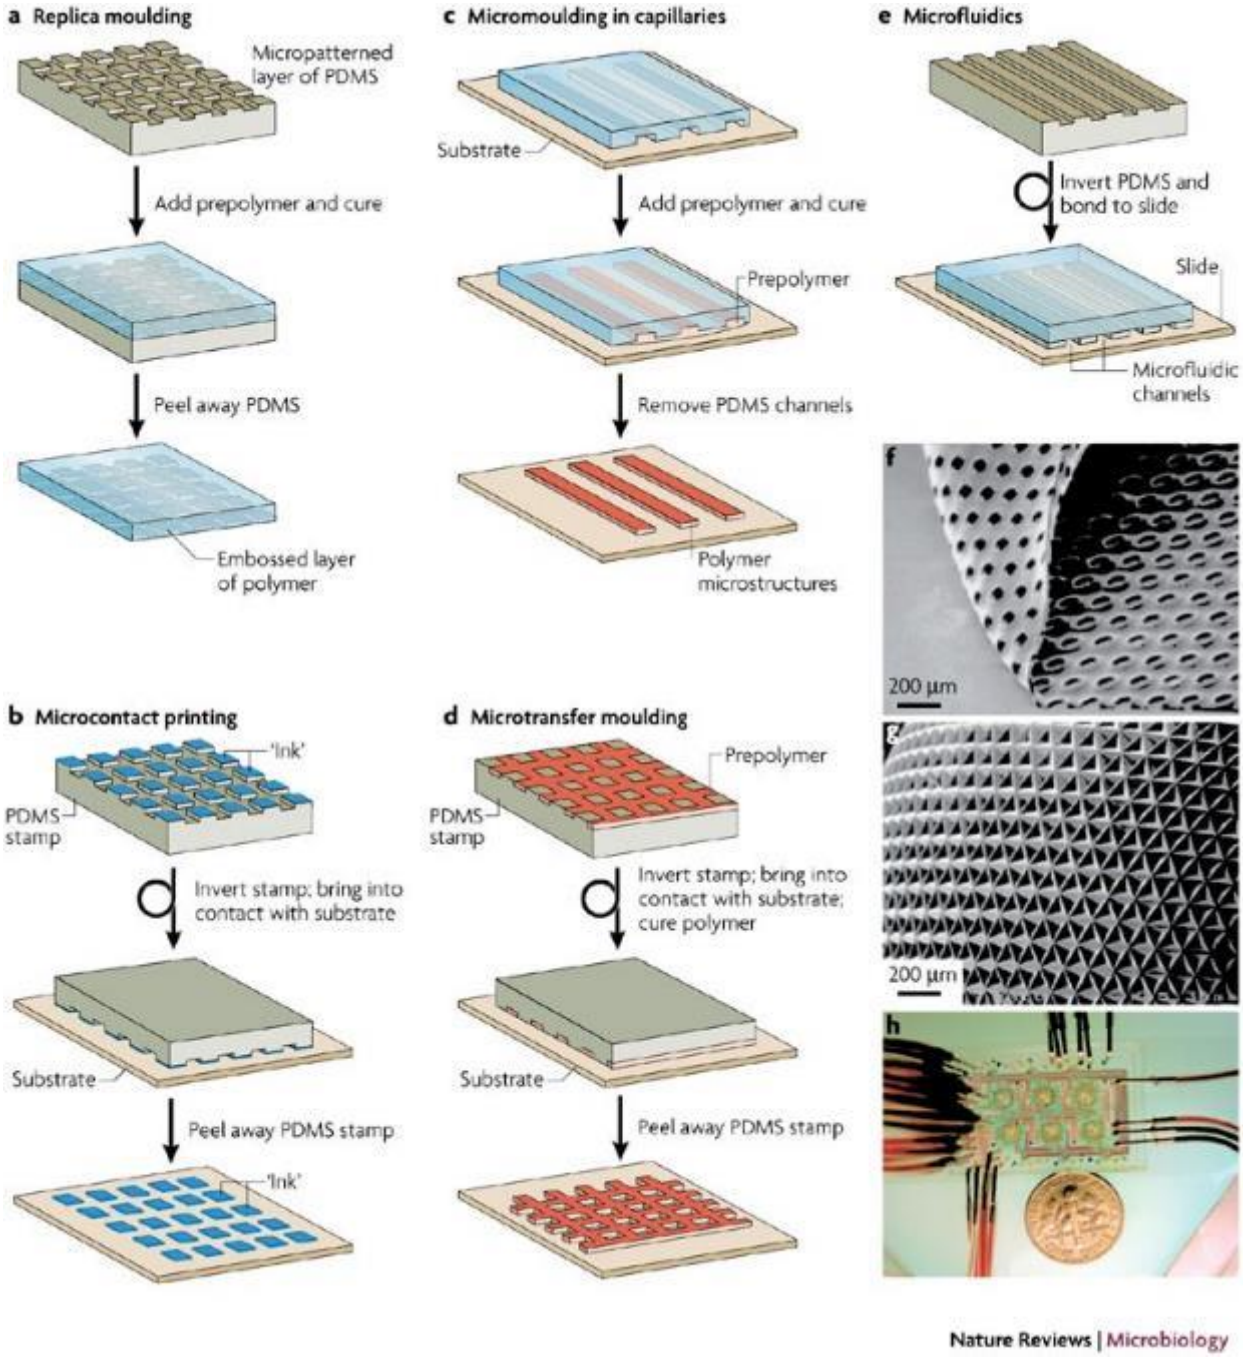
Positive and Negative Photoresist

Different chemicals may be used for permanently giving the material the desired property variations:

- Poly(methyl methacrylate) (PMMA)
- Poly(methyl glutarimide) (PMGI)
- Phenol formaldehyde resin (DNQ/Novolac)
- SU-8.







The key stages of each of the following techniques are shown: a | replica moulding; b | microcontact printing; c | micromoulding in capillaries; d | microtransfer moulding; and e | microfluidics. f | A PDMS membrane with microfabricated holes created by replica moulding from a master with circular posts. g | A curved layer of micropatterned polyurethane created by bending a micropatterned layer of PDMS and then replica moulding against it. h | A microfluidic chemostat for the growth and culture of microbial cultures. The device incorporates six reactors with an intricate network of plumbing, in a footprint that is approximatley 5 cm^2. PDMS, poly(dimethylsiloxane).

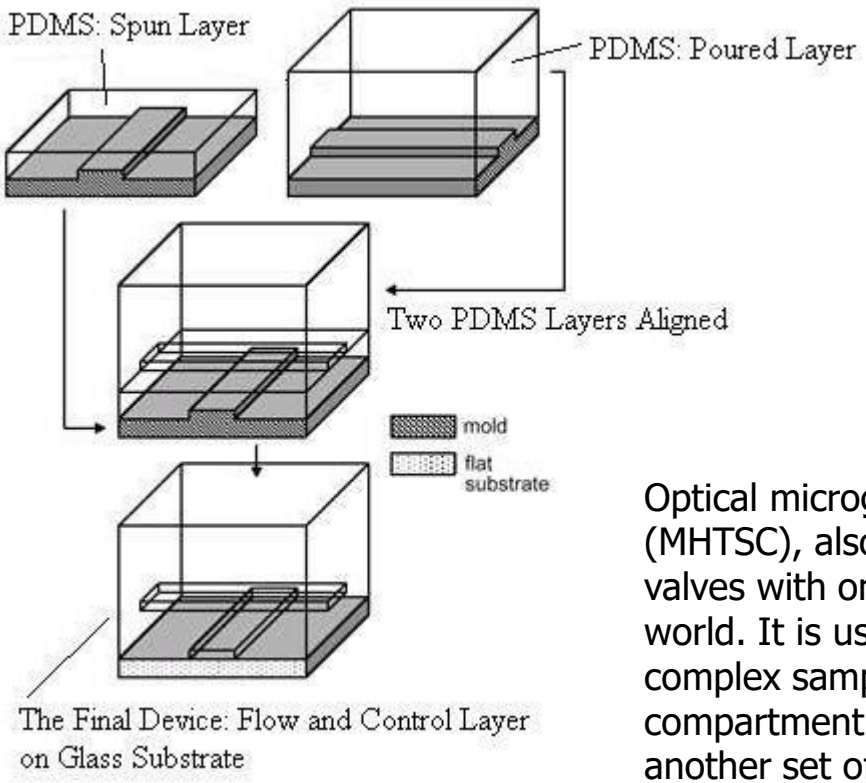
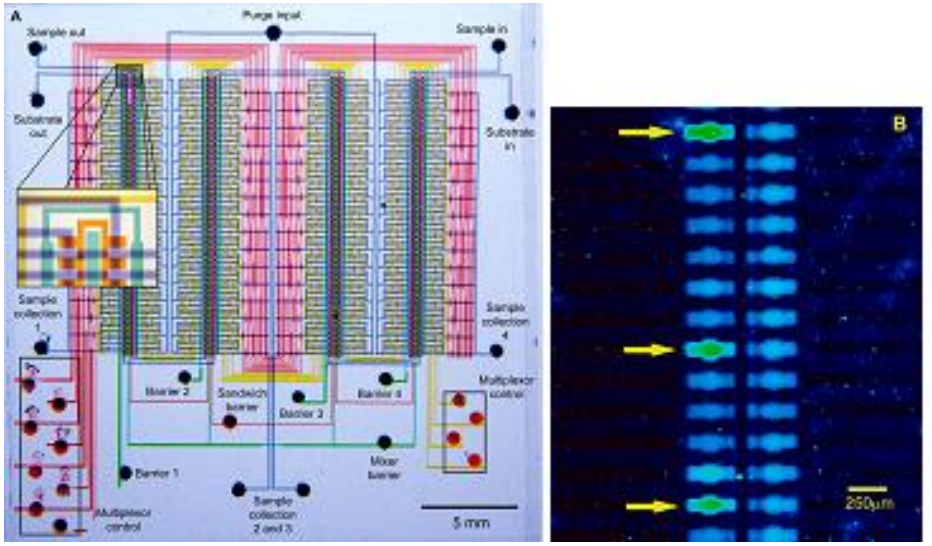
Quake Valve by Steven Quake





Optical micrograph of the Multiwell High Throughput Screening Chip (MHTSC), also referred to as a comparator array. This chip has 2,056 valves with only 18 valve control lines needed to interface to the outside world. It is used in high throughput screening applications and allows a complex sample to be segmented into many compartments; each compartment can then be assayed individually by pairwise mixing with another set of compartments containing, for example, fluorescent substrate. The chip occupies a total area of one square inch. This chip (without food dyes) was shown on the cover of the October 18, 2002 issue of Science . B. Portion of an image of the MHTSC chip taken with a DNA array scanner. A dilute sample of E. Coli bacteria expressing cytochrome C peroxidase (CCP) was segmented and then allowed to mix pairwise with the substrate Amplex Red.

Title: High-pressure needle interface for thermoplastic microfluidics

A simple, robust and low dead volume world-to-chip interface for thermoplastic microfluidics employing stainless steel needles has been developed. Using interference fit and threaded needles, the simple needle ports are compatible with internal chip pressures above 40 MPa with negligible dispersion for injected analyte bands.

Porous monoliths

Micropillar

Formed via water bath, UV irradiation or microwave etc.

(micromachined pillars of 5 µm diameter which were coated with a monolayer of C18)

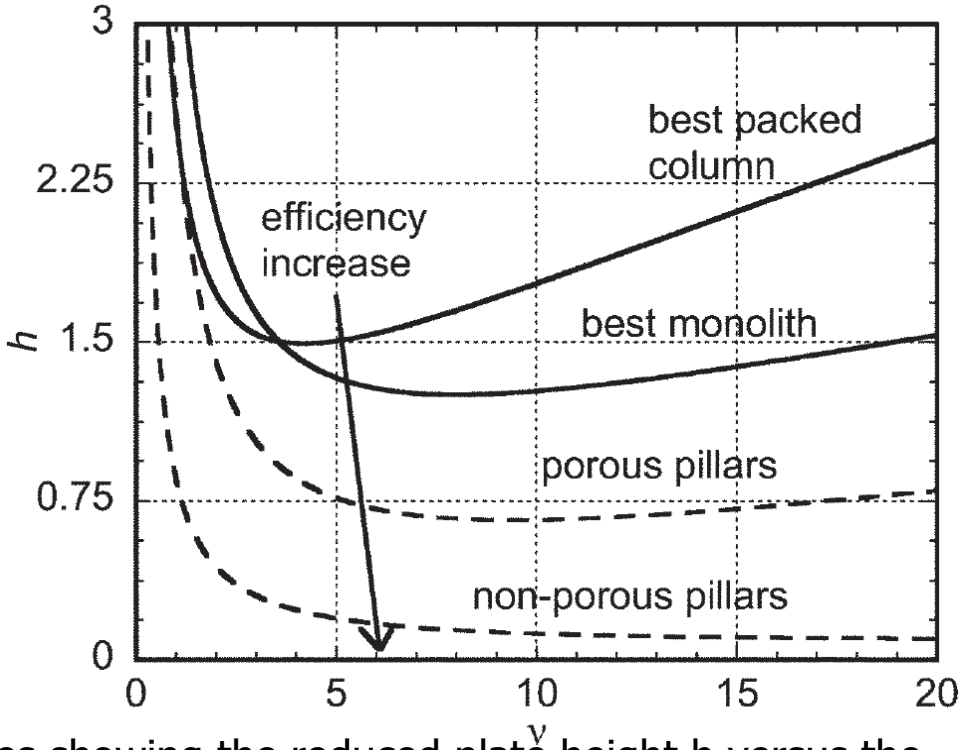
They found reduced plate heights between 0.2 (k' = 0) and 1.0 (k' = 2.17), i.e. close to the theoretical minimum for non-porous pillar columns

A Perfect Column - a Perfectly Ordered Column

$$h = \frac{B}{v} + Av^{1/3} + Cv$$

A, B and C are constants and v is the reduced velocity equal to ud_p/D_m with u (m s^{-1}) the mobile phase flow velocity, d_p (m) the particle diameter and D_m (m^2 s^{-1}) the diffusion coefficient of the analyte in the mobile phase. The value of B is determined by analyte diffusion in the axial direction of the column, the value of A by packing inhomogeneities that cause different flow paths for the mobile phase and the value of C by slow mass transfer in the stationary zone (either in pores or in the stationary phase)

Lab Chip, 2007, 7, 815–817



Curves showing the reduced plate height h versus the reduced mobile phase flow velocity v. Measured curves (drawn lines) for the best packed column (A = 0.5, B = 2 and C = 0.05) and the best monolith with a porosity of 0.8 (A = 0.32, B = 3.3 and C = 0.025); calculated curves (dotted lines) for a porous pillar array with a porosity of 0.8 and k' = 1.25 (A = 0.094, B = 2.495 and C = 0.021)13 and for an array of non-porous pillars with a porosity of 0.4 (A = 0.014, B = 0.84 and C = 0.001).

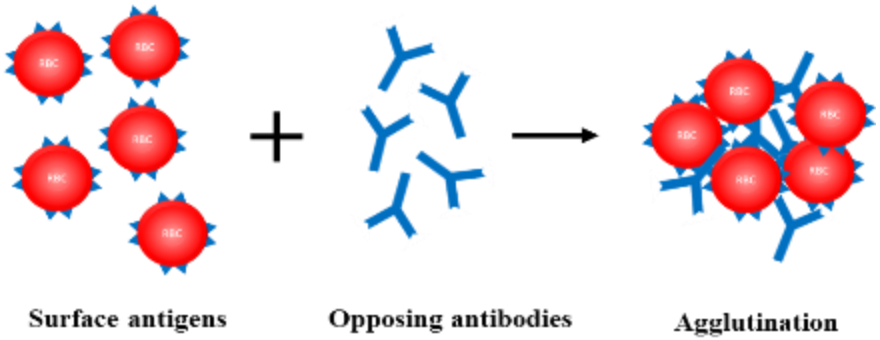
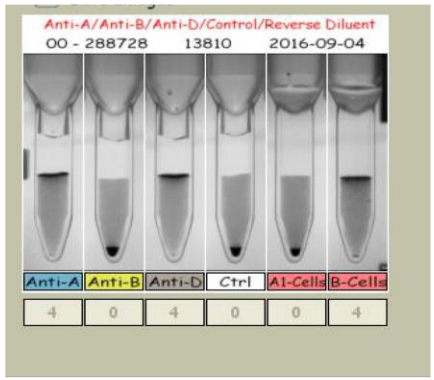
Traditional Blood Typing Tests in Hospital

- Conventional blood typing tests are reliable and accurate, but they also **require well-trained personnel and sophisticated equipment to obtain results**.
- In addition, typical agglutination tests require a blood sample of **more than 1 mL**, which cannot be obtained using low invasive methods, such as finger pricking.

- **Column agglutination**



2 USD



Rapid, accurate, and inexpensive blood typing tests are necessary for clinical confirmation on the battle filed or for infants that can't extract regular amount of blood.

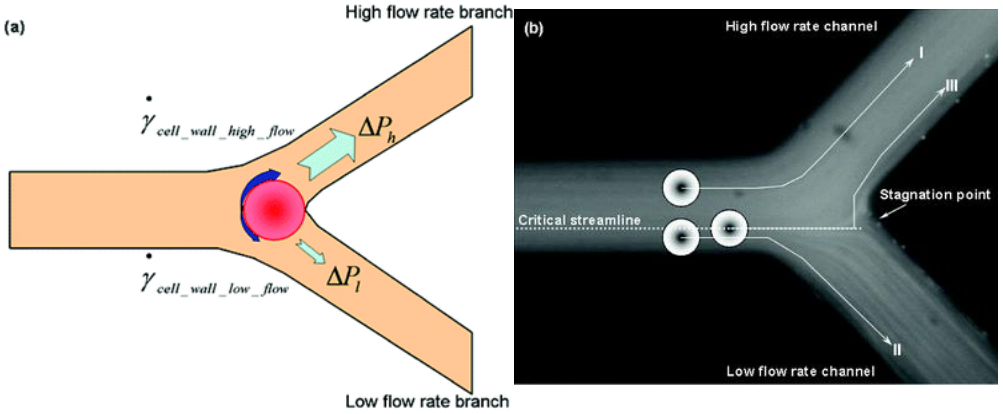
Cell/Plasma Separation



Scheme depicting plasma separation from a finger prick of blood by harnessing the Zweifach-Fung effect. Multiple DNA-encoded antibody barcode arrays are patterned within the plasma-skimming channels for in situ protein measurements.

R. Fan et al, *Nature biotechnology*, 2008, 26, 1373-1378.

(a) Schematic of the Zweifach–Fung effect; red blood cells have a tendency to travel into the higher flow rate daughter vessel with no cells travelling to the lower flow rate daughter vessel when the flow rate ratio is more than 2.5 and the cell-to-vessel diameter ratio is of the order of 1. The primary reason for this effect are because of differential pressure drops and shear forces acting on a cell. (b) An illustration of the critical streamline; A particle (I) whose centroid is beyond the critical streamline will travel into the high flow rate channel.
